

HIP TIPS ABOUT YOUR TIPS

- 1.** An air-tight seal between the tip and the ear canal is critical for proper bass response. Without an air-tight seal, you don't receive the signal as it was fully intended. Inside music gets out and outside noises get in. Leakage – any kind of leakage – isn't good. But we're talking about your ears here.
- 2.** The aforementioned air-tight seal may be improved by dampening either the tip or the ear canal before inserting the In-Ear Monitors (IEMs). Have a friend help by providing a wet-willy (or two, so both ears are covered).
- 3.** Go deep. IEMs need to be well-seated in the ear canal for proper sound.
- 4.** To ensure proper fit, start with the medium size tips. If they do not fully seat, move down a size. If they feel good, try the next size up as it may result in a better seal.
- 5.** Sliding out? Try a larger tip, a foam tip or a dual flange tip.
- 6.** Foam tips are less likely to slide out. Roll them between your index finger and thumb to make the diameter smaller first, then insert into your ear canal. It should go without saying, but one foam tip per ear. Hold them there as they expand and seal to your ear canal.
- 7.** Foam tips may change the sound slightly, but that's not necessarily a bad thing as some people prefer the change. What occurs is that high frequencies are reduced due to the sound absorption properties of the foam. The low frequencies may be reduced, as well, because the foam allows a slight bit of air leakage. There's that leakage talk again...
- 8.** We all have gunk in our ears. Yes, even you. Remove the tips and wash them (just the tips) regularly. We found that mild dishwashing soap and warm water works best. Not only will the IEM tips be clean again, but the frequency response will return to normal, too.
- 9.** Pulling the ear back with your arm on the opposite side around the back of the head can open the ear canal for good IEM insertion. This helps to fully seat the IEMs.
